0.2 4. Eigenvectors of the Gaussian Covariance Matrix

1. Find the mean in (R^2) of the sample.

```
[]: X_mu = np.mean(X,axis=0)
X_mu
```

- []: array([2.76916189, 5.24308424])
 - 2. Compute the 2x2 covariance matrix of the sample.

```
[ ]: X_covar = np.cov(X.T)
X_covar
```

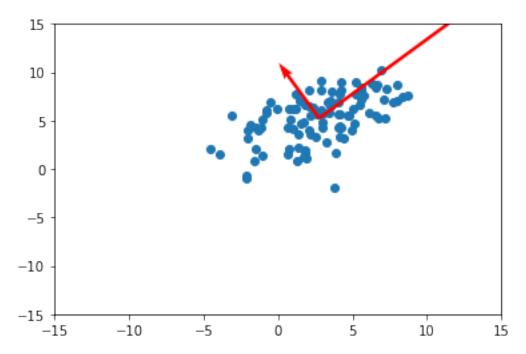

- - 3. Compute the eigenvectors and eigenvalues of this covariance matrix.

```
Here are the eigenvalues of the covariance matrix: [11.69812068 3.22418974] Here is the eigenbasis (normalized eigenvectors) of the covariance matrix: [[ 0.80671296 -0.59094349] [ 0.59094349 0.80671296]]
```

- 4. On a two-dimensional grid with a horizontal axis for X_1 with range [-15, 15] and a vertical axis for X_2 with range [-15, 15], plot
- i. all n = 100 data points, and
- ii. arrows representing both covariance eigenvectors. The eigenvector arrows should originate at the mean and have magnitudes equal to their corresponding eigenvalues.

The magnitude of eigenvector 1, 11.69812067707414, is equal to its corresponding eigenvalue, 11.69812067707414

The magnitude of eigenvector 2, 3.224189736737576, is equal to its corresponding eigenvalue, 3.224189736737576

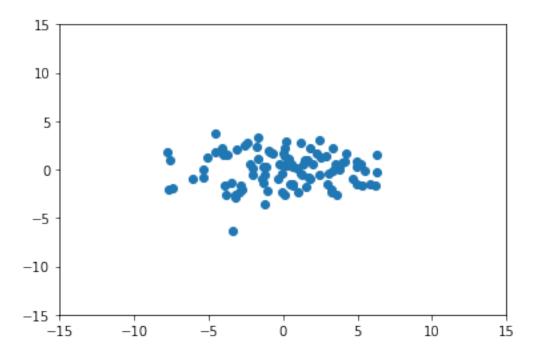

5. Let $U = [v_1, v_2]$ be a 2 x 2 matrix whose columns are the unit eigenvectors of the covariance matrix, where v_1 is the eigenvector with the larger eigenvalue. We use U^T as a rotation matrix to rotate each sample point from the (X_1, X_2) coordinate system to a coordinate system aligned with the eigenvectors. Center your sample points by subtracting the mean μ from each point; then rotate each point by U^T , gaiving $x_{rotated} = U^T(x - \mu)$. Plot these rotated points on a new two-dimensional grid, again with both axes having range [-15, 15].

```
[]: X_centered = np.empty_like(X).astype(float)
for i in range(100):
    X_centered[i][:] = X[i][:] - X_mu
X_centered.shape

X_rotated = X_centered @ covar_eigvecs
plt.scatter(X_rotated[:,0], X_rotated[:,1])
plt.axis([-15, 15, -15, 15])
```

[]: (-15.0, 15.0, -15.0, 15.0)

0.3 8. Gaussian Classifiers for Digits and Spam

```
[]: import numpy as np
import scipy as sp
from scipy import io
from scipy import stats
import pandas as pd
from sklearn.metrics import accuracy_score
```

First, we will load the MNIST data and hoild out 10,000 randomly chosen training points for a validation set.

```
[]: mnist = io.loadmat("data/%s_data.mat" % "mnist") # load the mnist data

# separate into training data, training labels, and testing data
mnist_raw_training_data = mnist["training_data"]
mnist_training_labels = mnist["training_labels"]
mnist_test_data = mnist["test_data"]

mnist_tuples = np.append(mnist_raw_training_data, mnist_training_labels, axis=1)
mnist_tuples_shuffled = np.random.permutation(mnist_tuples)

# In order to partition our data, we will use pandas; we will convert our numpy
→ array into a temporary
```

```
# dataframe and set aside the first 10,000 shuffled tuples, which will then be

⇒separated back into

# training data and training labels, to the validation set. Then we will assign

⇒the remainder, again

# separating the training data and training labels to the training set.

mnist_validation_data = mnist_tuples_shuffled[0:10000, 0:-1]

mnist_validation_labels = mnist_tuples_shuffled[0:10000, -1]

mnist_training_data = mnist_tuples_shuffled[10000:, 0:-1]

mnist_training_labels = mnist_tuples_shuffled[10000:, -1]
```

For whatever reason (I didn't have enough time, lmao), I decided not to vectorize contrast_normalizing an image and apply it to the data. I just wrote two separate functions, one that contrast-normalizes the entire training set and one that contrast-normalizes one image at a time.

- 8.1. The mean and covariance matrix for each class is returned by the build_gaussians function.
- 8.2. The LDA function will output the covariance matrix for the digit 0. We can see that the diagonal terms are greater than the off-diagonal terms, but not by much. We can conclude that our eigenvalues are very small values, so we may be dealing with a singular covariance matrix.

    # To add your own features, create a function that takes in the raw text and
    # word frequency dictionary and outputs a int or float. Then add your feature
    # in the function 'def generate_feature_vector'
    # The output of your file will be a .mat file. The data will be accessible using
    # the following keys:
          -'training_data'
           -'training_labels'
          -'test data'
    # Please direct any bugs to kevintee@berkeley.edu
